

Empathy Map

Devotee

Dimension	Observation
Says	"I want to know which slots are available before travelling."
Thinks	"Will seats still be available while I enter all traveller details?"
Does	Searches by temple/location, compares dates, enters devotee details, confirms the simulated checkout, prints a ticket.
Feels	Uncertain about queues; reassured by capacity, countdown, status, and ticket code.
Pain points	Travel uncertainty, limited visibility, repeated data entry, expired holds, unclear refund behavior.
Gains	Remote planning, transparent price/capacity, booking history, printable proof, donation receipt.

Temple organizer

Dimension	Observation
Says	"I need to publish capacity and see who booked."
Thinks	"Which temple and date require more slots?"
Does	Creates or deletes slots, reviews booking records, updates profile.
Feels	Responsible for capacity and schedule accuracy.
Pain points	The current model has no organizer ownership/assignment and shows global data.
Gains	One slot scheduler and consolidated registry.

Administrator

Dimension	Observation
Says	"I need control and a quick operational overview."
Thinks	"Which temples are popular, what revenue is recorded, and what facilities need work?"
Does	Filters/deletes users, creates/deletes temples, schedules events, tracks maintenance, views analytics.
Feels	Accountable for integrity, access, and reporting.
Pain points	No edit UI for several resources, no audit trail, no cascade cleanup, and insecure public role selection.

Dimension	Observation
Gains	Central management and summary metrics.

Design implications

- Keep temple/slot browsing public, but require authentication for state changes.
- Make availability and hold expiration prominent.
- Use server-authoritative prices, seat counts, roles, and status transitions.
- Associate every organizer with explicit temple IDs.
- Separate simulated checkout clearly from real payment.
- Add confirmation, audit history, notification, accessibility, and recovery flows before production use.
